Albany, New York 12201-0509

Nirav R. Shah, M.D., M.P.H.
Commissioner

Sue Kelly
Executive Deputy Commissioner

To: Laboratory Directors and Laboratory Staff
From: Robert Rej, Ph.D.
Date: March 7, 2011
Subject: Results of February 7, 2011 Hematology Proficiency Test

**International Normalized Ratio (INR) will be formally evaluated beginning June 2011.
Check your instrument and reagent entries for accuracy.**

Enclosed are results from the hematology proficiency testing survey shipped February 7, 2011. Five samples were distributed for each test category:

Routine Blood Counts (B41, B42, B43, B44, B45)

Routine Coagulation (C41, C42, C43, C44, C45- APTT, PT and Fibrinogen assays)

Cell Identification (341, 342, 343, 344, 345 - Images)

Evaluation of Proficiency Test Results:

Outlined below is a description of the process used to evaluate your laboratory's proficiency test results. A summary of your laboratory's performance for the three most recent surveys is also included with this report.

Target Value: When possible, targets utilized are derived from all-participant mean values calculated by a robust statistical technique. In some cases, however, it is recognized that reagent, and/or instrument specific targets may be required and "peer group" specific targets are used where appropriate. An asterisk placed adjacent to the manufacturer name or instrument name indicates that a peer group was used in establishing targets and acceptable ranges.

Not Gradable: Results for graded analytes for a few laboratories using unique instrument, reagent, or instrument/reagent combinations were considered "not gradable". For these laboratories pass credit (100%) has been issued. Since the laboratory is unable to participate in the NYS hematology proficiency test event as a graded participant, it is the responsibility of the laboratory to establish alternate means to verify the accuracy and precision of the test system for any ungraded analyte(s).

Acceptable Range: Represents limits established using criteria specified by CLIA '88 regulations, allowing for rounding to appropriate significant digits. Results falling within this range are scored as 100%. Any result exceeding these limits is considered unsatisfactory and receives a score of 0%.

Range Plots: The range plots graphically represent the relative distance of all results reported by your laboratory from the target value. Any result exceeding the high or low limit by >20% of the acceptable range is indicated by an asterisk (*).

Analyte Score: Scores for both individual samples and overall analyte performance are provided. Laboratories must achieve an overall analyte score >80% in order to meet performance criteria for that analyte.

Statistical Summary: Also enclosed is a statistical summary of participant data for the survey specimens. Mean and standard deviation (1 SD) values shown on the attached sheets are calculated by a robust statistical technique that does not assume a Gaussian distribution. Please note that standard deviation values are not used to determine acceptable ranges; CLIA '88 regulations established percentage limits for cellular and coagulation analytes.

Cellular Hematology (CBC): Results for individual instruments, where the number of laboratories using those systems is three or greater, are provided.

Coagulation: Results for individual instrument and reagent systems as well as instrument/reagent combinations, where the number of laboratories using those systems is three or greater, are provided.

The use of brand and/or trade names in this report does not constitute an endorsement of the products on the part of the Wadsworth Center or the New York State Department of Health.

So that this analysis can be as complete as possible, please review all future testings carefully and properly identify reagent and instrument systems used.

If you have any questions regarding these reports or wish to obtain an additional copy, please contact the Hematology Laboratory at (518) 474-9878. You may also contact us by E-mail: heme@wadsworth.org

World Wide Web: Results from this proficiency test event and selected previous proficiency test events are available on the Hematology and Clinical Chemistry web page at:

NEW YORK STATE HEMATOLOGY PROFICIENCY TESTING PROGRAM

February 7, 2011

Images on the Hematology and Clinical Chemistry web page: <http://www.wadsworth.org/chemheme/cellPT> were used to test all laboratories that perform manual white cell differentials. A summary of responses appear below, acceptable responses are shown in shaded areas.

Image 341

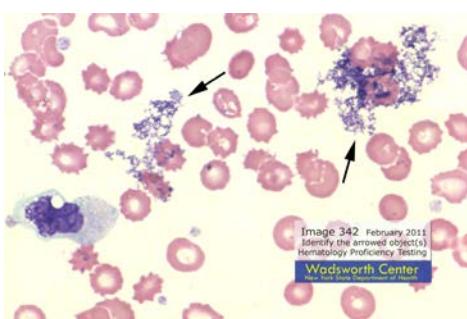

The nucleus of the arrowed cell in Image 341 is slightly indented and the chromatin is clumped. The cytoplasm is pink and contains fine granules. The cell, taken from a case of acute myelogenous leukemia, was correctly identified by 347 participants as a metamyelocyte.

"Normal metamyelocytes are smaller than myelocytes (diameter: 14-16 µm) and only slightly exceed the dimensions of band forms and segmented neutrophils. Metamyelocytes are incapable of division and lack the nucleoli, polysomes, and endoplasmic reticulum necessary for translation and continued protein synthesis". Jandle, J.H. Blood: Textbook of Hematology 2nd. Ed. Boston: Little, Brown and Company, 1996, p.618.

Number of Responses	Percent of Laboratories	Cell type or finding
347	94.0%	Metamyelocyte
15	4.1%	Band neutrophil
3	0.8%	Segmented/band neutrophil with toxic granulation
3	0.8%	Neutrophil with Pelger-Hüet nucleus
1	0.3%	Segmented neutrophil

Image 342

The arrowed bluish artifact in Image 342, obscuring some of the red blood cells, is precipitated stain as correctly identified by 99.5% of participants. In some instances clumps of stain precipitate may appear similar in appearance to bacteria or red blood cell inclusions and differentiation of these choices is essential. Stain precipitate appears as very intensely stained randomly shaped clumps or aggregates, bacteria or red cell inclusions on the other hand have specific morphological form.

Two participants identified the arrowed objects as platelet clumps. Platelet clumps are aggregates of individual platelets most commonly discovered by manual confirmation of a false low automated platelet count. Platelet clumping is caused by platelet-specific agglutinins and, more commonly, is related to the anticoagulant EDTA. An image of platelet clumping was administered to participants as an educational challenge in May 2004 (Image E09) <http://www.wadsworth.org/chemheme/heme/ptframes.htm>. The individual platelets that form the aggregate are clearly visible in Image E09 unlike the random shape of stain precipitate.

Number of Responses	Percent of Laboratories	Cell type or finding
367	99.5%	Stain precipitate
2	0.5%	Platelet clump(s)

Image 343

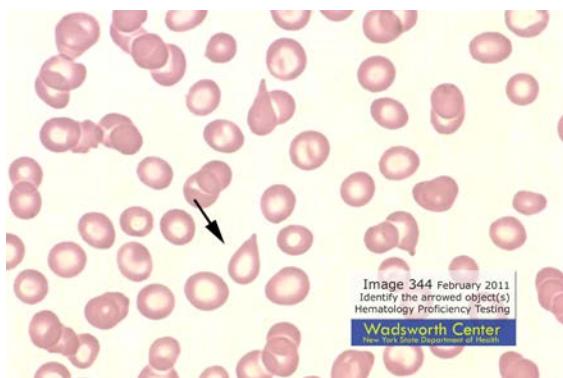

The nucleus of the arrowed cell in Image 343 is a homogeneous blue-black mass with no structure. The cytoplasm is mostly blue in color. The cell is a nucleated red blood cell and was correctly identified by all participants.

Nucleated red blood cells are usually seen in newborn infants and in patients with responses to hemolytic crisis. The diagnosis in this case, of which Image 343 was taken, is microangiopathic hemolytic anemia. There are many causes of microangiopathic hemolytic anemia some of which include disseminated intravascular coagulation (infections, obstetric disorders), malignant hypertension, chemotherapy-induced disease, thrombotic thrombocytopenic purpura, hemolytic uremic syndrome and immunologic vasculitis (disseminated lupus erythematosus, acute glomerulonephritis, homograft rejection).

Number of Responses	Percent of Laboratories	Cell type or finding
369	100%	Nucleated red cell

Image 344

The arrowed cell in Image 344 is round on one end and elongated on the other, the elongated end is pointed forming the classic tear drop appearance. The cell in Image 344 was correctly identified as a tear drop cell (dacrocyte) by 367 participants. The presence of tear drop shaped red blood cells indicates conditions associated with an abnormal spleen or bone marrow where the cells become distorted as they maneuver out into the circulation. Such conditions include this case of thalassemia as well as myelofibrosis, pernicious anemia, hemolytic anemias and bone marrow infiltration by malignancy.

Number of Responses	Percent of Laboratories	Cell type or finding
367	99.5%	Tear drop cell (dacrocyte)
2	0.5%	Target cell (codocyte)

Hematology Proficiency Testing
Wadsworth Center
New York State Department of Health

The conspicuous nucleolus in the center of the nucleus of the arrowed cell in Image 345, in addition to the overall large size of the cell and the smooth chromatin, make identification of this cell as a blast cell the best choice.

Image 345 was taken from a suspected case of monocytic leukemia obtained from an 89 year-old female who presented with fever, ecchymoses and severe diarrhea. Laboratory data included an increased white blood cell count ($34.0 \times 10^9/L$) and a decreased platelet count ($12 \times 10^9/L$). Given the diagnosis of this case, the arrowed blast cell in Image 345 is likely a monoblast. Definitive diagnosis is almost impossible by examination of the peripheral smear alone, therefore, acceptable responses included monoblast, myeloblast, lymphoblast and blast cell, not classified.

Number of Responses	Percent of Laboratories	Cell type or finding
320	86.7%	Blast cell, not classified
7	1.9%	Monoblast
7	1.9%	Myeloblast
31	8.4%	Reactive/Atypical lymphocyte
4	1.1%	Lymphoblast
